Unijunction Transistor (UJT)

- A unijunction transistor (UJT) is a three terminal semiconductor switching device.
- This device has a unique characteristics that when it is triggered, the emitter current increases re-generatively until it is limited by emitter power supply.
- Due to this characteristics, the unijunction transistor can be employed in a variety of applications e.g., switching, pulse generator, saw-tooth generator etc.

Construction of UJT

- It consists of an n-type silicon bar with an electrical connection on each end.
- The leads to those connections are called base leads, i.e., base-one $B_1$ and base-two $B_2$.
- Part way along the bar between the two bases, nearer to $B_2$ than $B_1$, a pn junction is formed between a p-type emitter and the bar.
- The lead to this junction is called the emitter lead E.
- Next figure shows the symbol of unijunction transistor. Note that emitter is shown closer to $B_2$ than $B_1$. 
Unijunction Transistor (UJT)

- The following points may be noted about the UJT:
  - Since the device has one pn junction and three leads, it is commonly called a unijunction transistor.
  - With only one pn junction, the device is really a form of diode. Because the two base terminals are taken from one section of the diode, this device is also called double-based diode.
  - The emitter is heavily doped having many holes. The n-region, however, is lightly doped. For this reason, the resistance between the base terminals is very high when emitter lead is open.

Equivalent Circuit of a UJT

- The resistance of the silicon bar is called the inter-base resistance $R_{BB}$. It is represented by two resistors in series such as:
  - $R_{B2}$ is the resistance of silicon bar between $B_2$ and the point at which the emitter junction lies.
  - $R_{B1}$ is the resistance of the bar between $B_1$ and emitter junction. This resistance is shown variable because its value depends upon the bias voltage across the pn junction.
- The pn junction is represented in the emitter by a diode D.

Operation of UJT

- The device has normally $B_2$ positive with respect to $B_1$.
- If voltage $V_{BB}$ is applied between $B_2$ and $B_1$ with emitter open, a voltage gradient is established along the n-type bar.

Operation of UJT

- Since the emitter is located nearer to $B_2$, more than half of $V_{BB}$ appears between the emitter and $B_1$.
- The voltage $V_1$ between emitter and $B_1$ establishes a reverse bias on the pn junction and the emitter current is cut off.
- Of course, a small leakage current flows from $B_2$ to emitter due to minority carriers.
Operation of UJT

- If a positive voltage is applied at the emitter, the pn junction will remain reverse biased so long as the input voltage is less than $V_{1}$.
- If the input voltage to the emitter exceeds $V_{1}$, the pn junction becomes forward biased.
- Under these conditions, holes are injected from p-type material into the n-type bar.

Operation of UJT

- These holes are repelled by positive $B_2$ terminal and they are attracted towards $B_1$ terminal of the bar.
- This accumulation of the holes in the emitter to $B_1$ region results in the decrease of resistance in this section of the bar.
- The result is that internal voltage drop from emitter to $B_1$ is decreased and hence the emitter current $I_e$ increases.

Operation of UJT

- As more holes are injected, a condition of saturation will eventually be reached.
- At this point, the emitter current is limited by emitter power supply only. The device is now in the ON state.
- If a negative pulse is applied to the emitter, the pn junction is reverse biased and the emitter current is cut off. The device is then said to be in the OFF state.

Explanation - Equivalent Circuit

- The circuit action of a UJT can be explained more clearly from its equivalent circuit.
- With no voltage applied to the UJT, the inter-base resistance is given by:
  \[ R_{BB} = R_{B1} + R_{B2} \]
- If a voltage $V_{BB}$ is applied between the bases with emitter open, the voltage will divide up across $R_{B1}$ and $R_{B2}$.
- Voltage across $R_{B1}$,
  \[ V_1 = \frac{R_{B1}}{R_{B1} + R_{B2}} V_{BB} \]
- or
  \[ \eta = \frac{V_1}{V_{BB}} = \frac{R_{B1}}{R_{B1} + R_{B2}} \]
Explanation - Equivalent Circuit

• The ratio $V_1/V_{BB}$ is called **intrinsic stand-off ratio** and is represented by $\eta$. The value of $\eta$ lies between 0.51 and 0.82.
• So voltage across $R_{B1}$, $V_1 = \eta V_{BB}$
• The voltage $\eta V_{BB}$ appearing across $R_{B1}$ reverse biases the diode. Therefore, the emitter current is zero.

Explanation - Equivalent Circuit

• If now a progressively rising voltage is applied to the emitter, the diode will become forward biased when input voltage exceeds $\eta V_{BB}$ by $V_D$, the forward voltage drop across the silicon diode, i.e.

$$V_p = \eta V_{BB} + V_D$$

where $V_p$ = Peak point voltage
$V_D$ = forward voltage drop across silicon diode ($\approx 0.7$ V)

Conclusion

• When the input positive voltage to the emitter is less than peak-point voltage $V_p$, the pn junction remains reverse biased and the emitter current is practically zero.
• However, when the input voltage exceeds $V_p$, $R_{B1}$ falls from several thousand ohms to a small value. The diode is now forward biased and the emitter current quickly reaches to a saturation value limited by $R_{B1}$ and forward resistance of pn-junction.
UJT Characteristics

• First curve shows the curve between emitter voltage ($V_E$) and emitter current ($I_E$) of a UJT at a given voltage $V_{BB}$ between the bases. This is known as the emitter characteristics of UJT.

• The following points may be noted from the characteristics.

  • Initially, in the cut-off region, as $V_E$ increases from zero, slight leakage current flows from terminal $B_2$ to the emitter.
  • This current is due to the minority carriers in the reverse biased diode.

Characteristic of UJT

• Above a certain value of $V_E$, forward $I_E$ begins to flow, increasing until the peak voltage $V_P$ and current $I_P$ are reached at point $P$.
• After the peak point $P$, an attempt to increase $V_E$ is followed by a sudden increase in emitter $I_E$ with a corresponding decrease in $V_E$.
• This is negative resistance portion of the curve.
Characteristic of UJT

- The negative portion of the curve lasts until the valley point \( V \) is reached with valley-point voltage \( V_v \) and valley-point current \( I_v \).
- After the valley point, the device is driven to saturation.

![Image of UJT characteristic curve]

Characteristic of UJT

- The figure shows the typical family of \( V_E \) vs \( I_E \) characteristics of a UJT at different voltages between the bases.
- It is clear that peak-point voltage \( V_p \) falls steadily with reducing \( V_{bb} \) and so does the valley point voltage \( V_v \).
- The difference \( V_p - V_v \) is a measure of the switching efficiency of UJT and can be seen to fall off as \( V_{bb} \) decreases.

Unijunction Transistor Applications

- The most common application of a unijunction transistor is as a triggering device for SCR’s and Triacs but other UJT applications include saw-toothed generators, simple oscillators, phase control, and timing circuits.
- The simplest of all UJT circuits is the Relaxation Oscillator producing non-sinusoidal waveforms and overvoltage detector.

Characteristic of UJT

- Three important parameters for the UJT are \( I_p \), \( V_v \), and \( I_v \) and are defined below:
  - **Peak-Point Emitter Current, \( I_p \):** It is the emitter current at the peak point. It represents the minimum current that is required to trigger the device (UJT). It is inversely proportional to the inter-base voltage \( V_{bb} \).
  - **Valley Point Voltage, \( V_v \):** The valley point voltage is the emitter voltage at the valley point. The valley voltage increases with the increase in inter-base voltage \( V_{bb} \).
  - **Valley Point Current, \( I_v \):** The valley point current is the emitter current at the valley point. It increases with the increase in inter-base voltage \( V_{bb} \).
Silicon Controlled Rectifier (SCR)

- Silicon Controlled Rectifier (SCR) is a unidirectional semiconductor device made of silicon.
- This device is the solid state equivalent of thyatron and hence it is also referred to as thyristor.
- In fact, SCR (Silicon Controlled Rectifier) is a trade name given to the thyristor by General Electric Company.
- SCRs are mainly used in electronic devices that require control of high voltage and power.
- This makes them applicable in medium and high AC power operations such as motor control function.
- An SCR conducts when a gate pulse is applied to it, just like a diode.

An SCR can be considered as two interconnected transistors.
- It is seen that a single SCR is the combination of one pnp transistor (Q₁) and one npn transistor (Q₂).
- Here, the emitter of Q₁ acts as the anode terminal of the SCR while the emitter of Q₂ is its cathode.
- Further, the base of Q₁ is connected to the collector of Q₂ and the collector of Q₁ is connected to the base of Q₂.
- The gate terminal of the SCR is connected to the base of Q₂, too.
Reverse Blocking Mode of SCR

- In this mode, the SCR is reverse biased by connecting its anode terminal (A) to negative end and the cathode terminal (K) to the positive end of the battery.
- This leads to the reverse biasing of the junctions J1 and J3, which in turn prohibits the flow of current through the device, in spite of the fact that the junction J2 remains in forward biased condition.

Forward Blocking Mode of SCR

- Here a positive bias is applied to the SCR by connecting anode terminal (A) to the positive and cathode terminal (K) to the negative terminal of the battery, as shown in the figure below.
- Under this condition, the junction J1 and J3 get forward biased while junction J2 gets reverse biased.
- Here also current cannot pass through the SCR except the tiny current flowing as saturation current as shown in the characteristics curve.

Characteristics of SCR

- In this state, the SCR behaves as a typical diode.
- In this reverse biased condition, only reverse saturation current flows through the device as in the case of the reverse biased diode which is shown in the characteristic curve.
- The device also exhibits the reverse breakdown phenomenon beyond a reverse safe voltage limit just like a diode.
Forward Conduction Mode of SCR

- The SCR can be made to conduct either.
  - By increasing the positive voltage applied at anode terminal (A) beyond the Break Over Voltage, \( V_B \).
  - By applying positive voltage at the gate terminal (G) as shown in the figure below.

Forward Conduction Mode of SCR

- In the first case, the increase in the applied bias causes the initially reverse biased junction \( J_2 \) to break down at the point corresponding to forward Break Over Voltage, \( V_B \).
- This results in the sudden increase in the current flowing through the SCR as shown in the characteristic curve, although the gate terminal of the SCR remains unbiased.

Forward Conduction Mode of SCR

- However, SCR can also be turned on at a much smaller voltage level by proving small positive voltage at the gate terminal.
- The reason behind this can be better understood by considering the transistor equivalent circuit of the SCR shown in the figure.

Forward Conduction Mode of SCR

- Here it is seen that on applying a positive voltage at the gate terminal, transistor \( Q_2 \) switches ON and its collector current flows into the base of transistor \( Q_1 \).
- This causes \( Q_1 \) to turn ON which in turn results in the flow of its collector current into the base of \( Q_2 \).
- This causes either transistor to get saturated at a very rapid rate and the action cannot be stopped even by removing the bias applied at the gate terminal, provided the current through the SCR is greater than that of the Latching current.
- Here the latching current is defined as the minimum current required to maintain the SCR in conducting state even after the gate pulse is removed.
**Forward Conduction Mode of SCR**

- In such state, the SCR is said to be latched and there will be no means to limit the current through the device, unless by using an external impedance in the circuit.
- This technique reduces the anode current below the **Holding Current**.
- Holding current is defined as the **minimum current** to maintain the SCR in its conducting mode, in presence of gate pulse.

**Phototransistor**

- A **Phototransistor** is an electronic switching and current amplification component which relies on exposure to light to operate.
- When light falls on the junction, reverse current flows which is proportional to the luminance.
- Phototransistors are used extensively to detect light pulses and convert them into digital electrical signals.
- These are operated by light rather than electric current.
- Providing large amount of gain, low cost and these phototransistors might be used in numerous applications.

**Phototransistor**

- **Phototransistors** are transistors with the base terminal exposed to light. Instead of sending current into the base, the photons from striking light activate the transistor.
- This is because a phototransistor is made of a bipolar semiconductor and focuses the energy that is passed through it.
- The structure of the **phototransistor** is specifically optimized for photo applications. These devices can be either **homojunction** structured or **heterojunction** structured.
- Compared to a normal transistor, a photo transistor has a larger base and collector width and is made using diffusion.

---

**Figure 1**

- [Phototransistor Symbol with (a) Three Leads (b) Two Leads](#)
Phototransistor

- In a Photo-transistor the base current is produced when light strikes the photosensitive semiconductor base region.
- The collector-base \( p\!n \) junction is exposed to incident light through a lens opening in the transistor package.
- When there is no incident light, there is only a small thermally generated collector-to-emitter leakage current, \( I_{CEO} \).
- This dark current, \( I_d \), is produced that is directly proportional to the light intensity.
- This action produces a collector current that increases with \( I_d \).
- Except for the way base current is generated, the phototransistor behaves as a conventional BJT. In many cases, there is no electrical connection to the base.

Phototransistor

• The relationship between the collector current and the light-generated base current in a phototransistor is:

\[
I_c = \beta_{DC} I_d
\]

• The schematic symbol and some typical photo-transistors are shown.

Phototransistor

• Phototransistors are either tri-terminal (emitter, base and collector) or bi-terminal (emitter and collector) semiconductor devices which have a light-sensitive base region.
• In the three-lead configuration, the base lead is brought out so that the device can be used as a conventional BJT with or without the additional light-sensitivity feature.
• In the two-lead configuration, the base is not electrically available, and the device can be used only with light as the input.
• In many applications, the phototransistor is used in the two-lead version.

Phototransistor

• Since the actual photo-generation of base current occurs in the collector-base region, the larger the physical area of this region, the more base current is generated.
• Thus, a typical phototransistor is designed to offer a large area to the incident light.
Phototransistor

- A phototransistor with a biasing circuit and typical collector characteristic curves.
- Each curve on the graph corresponds to a certain value of light intensity and that the collector current increases with light intensity.
- Phototransistors are not sensitive to all light but only to light within a certain range of wavelengths.
- They are most sensitive to particular wavelengths in the red and infrared part of the spectrum, as shown by the peak of the infrared spectral response curve.

Collector Characteristic

Applications of Phototransistor

- Object detection
- Encoder sensing
- Automatic electric control systems such as in light detectors
- Security systems
- Punch-card readers
- Relays
- Computer logic circuitry
- Counting systems
- Smoke detectors
- Laser-ranging finding devices
Applications of Phototransistor

- Optical remote controls
- CD players
- Astronomy
- Night vision systems
- Infrared receivers
- Printers and copiers
- Cameras as shutter controllers
- Level comparators
